1. Assume a monopolist faces a market demand curve $p = 100 - 2Q$, and has a short-run total cost function $c(Q) = 640 + 20Q$. What is the profit-maximizing level of output? What are the profits? Graph the marginal revenue, marginal cost, and demand curves, and show the area that represents deadweight loss on the graph.

2. A monopolist sells in two states and practices price discrimination by charging separate prices in each state. The monopolist produces at constant marginal cost $MC = 10$. Demand in market 1 is $Q_1 = 50 - p_1$. Market 2 demand is $Q_2 = 90 - 1.5p_2$. What price will be charged in each market?
